Physical and Psychological Problems after Critical Illness
Prediction, Detection and Treatment

AKADEMISK AVHANDLING
som för avläggande av medicine doktorsexamen vid Karolinska Institutet
offentligen försvaras i Nanna Svartz Auditorium (A7:00), Karolinska
Universitetssjukhuset Solna.

Fredagen den 14 juni, 2013, kl 09.00

av
Anna Schandl
Leg Sjuksköterska

Huvudhandledare:
Med. Dr. Peter Sackey
Karolinska Institutet
Institutionen för Fysiologi och Farmakologi
Sektionen för Anestesi och Intensivvård

Bihandledare:
Professor Matteo Bottai
Karolinska Institutet
Institutionen för Miljömedicin
Enheten för Biostatistik

Professor Örjan Sundin
Mittuniversitetet Östersund
Institutionen för Samhällsvetenskap
Avdelningen för Psykologi

Fakultetsopponent:
Professor Anders Larsson
Uppsala Universitet
Institutionen för Kirurgiska vetenskaper

Betygsnämnd:
Docent Lars Berggren
Örebro Universitet
Institutionen för Kirurgi

Docent Sten Walther
Linköping Universitet
Institutionen för Medicin och Hälsa

Docent Karin Samuelson
Lunds Universitet
Institutionen för Hälsa, Vård och Samhälle

Stockholm 2013
ABSTRACT

The prevalence of physical and psychological problems after critical illness is high. To improve long-term outcome in Intensive Care Unit (ICU) survivors, follow-up programmes are under development. However, the optimal organization, duration and content of ICU follow-up has not yet been established and the efficacy of ICU follow-up is uncertain.

A new multidisciplinary model for helping ICU survivors by identifying and managing untreated physical and psychological problems was developed. Findings from the first year of follow-up were described and treatment effects of this interventional follow-up were evaluated. Novel methods for predicting patients at risk for physical and psychological problems following critical illness were investigated.

Multidisciplinary screening and treatment of problems was feasible in identifying and helping ICU survivors with untreated physical and psychological problems. Patients screened and treated in the first six months appeared to have little need for further ICU follow-up. Women reported more psychological problems than men after critical illness and multidisciplinary ICU follow-up reduced the prevalence of more severe symptoms of post-traumatic stress and depression in women. Predictive models for use at ICU discharge, separately screening for physical disability and psychological morbidity were developed. Weighted predictors for estimation of the probability of physical or psychological problems two months after ICU discharge were included in the two screening instruments. Significant predictors for new-onset physical disability were low education level, reduced core stability, fractures and an ICU stay >48 hours. Predictors for psychological morbidity were major pre-existing disease, being a parent to children <18 years of age, previous psychological problems, in-ICU agitation, being unemployed or on sick-leave prior to ICU admission and exhibiting depressive symptoms in the ICU. Both instruments had fair predictive accuracy in identifying ICU survivors with morbidity after ICU stay and performed better than ICU length of stay as a method of selecting patients with likely need for support.
